

## Check Exchange 2007 with PowerShell - Part 2

We will continue to look at some of the 'test' commands available in Exchange 2007, see what they can do and how to use them.

Check Exchange 2007 with PowerShell - Part 1

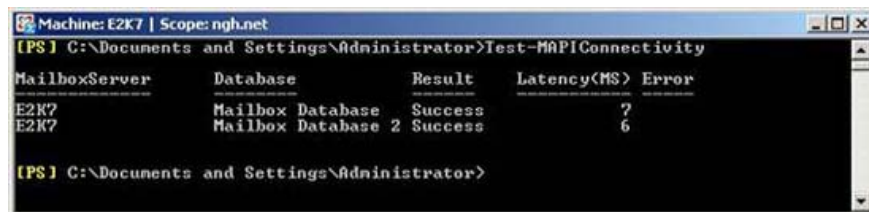

*Neil Hobson*

**Network Administration** - *In part 1 of this two-part series, I talked about Exchange Management Shell commands starting with Test- which can be used to test the configuration and operation of machines. Exchange 2007 server. These commands can also be used to help resolve problems that occur after servers are placed into the production environment. In the first section, we learned about the Test-ServiceHealth and Test-OutlookWebServices commands. In this section, we will show you the Test-MAPICConnectivity, Test-ExchangeSearch, Test-OwaConnectivity, Test-WebServicesConnectivity, Test-PopConnectivity and Test-ImapConnectivity commands.*

**Test-MAPICConnectivity**

Perhaps the most obvious connection method for a client is through MAPI, with this connection, there is a simple test done through the *Test-MAPIConnectivity* command. This command needs to log into a mailbox to test the functionality and so you can use the *-Identity parameter* to identify this target mailbox. That said, if you do not specify a specific mailbox, this command will log into the *SystemMailbox* found in each database.

You also need to specify the *-Database* parameter to distinguish the databases that you like to log into. If ignored, all databases on the internal server will be logged. As with many other commands, you can use the *-Server* parameter to control which server you like to test. The output you get from this command is shown in Figure 6. This command has no additional parameters provided, which means that both databases are logged on the mailbox server. internal. Notice the delay information provided, it shows you the delay during login to each mailbox.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-MAPIConnectivity
MailboxServer      Database          Result            Latency(MS)  Error
-----
E2K7                Mailbox Database  Success           7
E2K7                Mailbox Database 2 Success           6
[PS] C:\Documents and Settings\Administrator>
```

Figure 6: Output of Test-MAPIConnectivity

If any problem occurs during the mailbox login process, the *Result* column will display the word *\* FAILURE \** and the *Error* column will give you a detailed description of the error.

### Test-ExchangeSearch

Some things related to checking the connectivity of mailboxes are checking the content indexing to function properly. The *Test-ExchangeSearch* command can be used for this process and will work by creating a message with an attachment, which can only be found through Exchange Search. Because indexing of content is enabled by default in Exchange 2007, you need to check the information promptly before putting the server into real use in a production environment. The structure of this command to use is simple:

*Test-ExchangeSearch -Server*

Figure 7 shows the result of executing this command in the absence of any additional parameters provided. As you can see, this command is looking for the SystemAttendant mailbox and is being searched on the internal mailbox server because no *-Server* parameter is provided.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-ExchangeSearch

TestSearch
Running a search test in user "SystemAttendant" mailbox.
to
```

Figure 7: Process of Test-ExchangeSearch command

At the end of the process, the results will be displayed and as you can see from Figure 8, there is an item found successfully in the 9s time period. One of the main parameters for this command is the *-IndexingTimeout* parameter, which controls the amount of time that the process will wait while searching for an item before returning an error message. The default setting of 120s will be a reasonable time for such a test. If you notice below this number, the command will start the search as shown in Figure 7 and, if this time is exceeded, the search will be stopped immediately and returned a screen The status image is shown in Figure 8, when the *ResultFound* column shows *False* and the *SearchTime* column represents a value of *-1*.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-ExchangeSearch

ResultFound SearchTime
-----
True 9

[PS] C:\Documents and Settings\Administrator>
```

Figure 8: Output of Test-ExchangeSearch command

## Test-OwaConnectivity

*Test-OwaConnectivity* is a more complex command during use. The reason we say this is because there are more parameters that can be used with this command than the other commands introduced to you in this article. The main purpose, this command is used to check all OWA virtual directories on a Client Access Server or a URL. Let's take a look at an example of a URL. To test a URL, there are two main parameters to consider here. These parameters are *-URL* and *-TestType*. The *-URL* parameter specifies the OWA URL you want to check, while the *-TestType* parameter can be used to check the internal or external OWA URL. By default, the *-TestType* parameter checks the internal URL, but you can configure it to check the external URL by entering the *parameter -TestType: External*.

We need to consider the information that will be used to log in and check for OWA connectivity. This is done through the *-MailboxCredential* parameter, which will bring up an *authentication* window for you to enter your account information. One final parameter worth considering is *-TrustAnySSLCertificate*, which is useful when you check internal URLs because in these cases, it is typical for a valid certificate name with an external URL,

not right URL inside. This parameter will effectively guarantee errors. Let's take a closer look in one case where we will examine the internal internal URL of an Exchange 2007 server named E2K7 using the administrator account information and any SSL certificates. any authentication. The command to be used is:

*Test-OwaConnectivity -URL https://E2K7/owa -MailboxCredential (Get-Credential Listening Administrator) -TrustAnySSLCertificate*

The output of the command is shown in Figure 9.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-OwaConnectivity -URL https://e2k7/owa -MailboxCredential (Get-Credential NGH\Administrator) -TrustAnySSLCertificate
ClientAccessServer MailboxServer URL Scenario Result Latency Error
-----
https://e2k7/owa/ Logon Success 70.1
[PS] C:\Documents and Settings\Administrator>
```

Figure 9: Output of Test-OwaConnectivity command

As with many of the other commands detailed in this article, you can see the process delay being displayed with an error or success. If we have chosen not to enforce the authentication of the SSL certificate and our certificate has a different name than the one used in the -URL parameter, then we will get a warning error below. :

*'WARNING: ?ã th? không th? ??ng nh?p vào Outlook Access Web vì SSL certificate không h?p l?.'*  
*'Warning: The test process cannot log into Outlook Web Access because the SSL certificate is invalid'*

This is shown in Figure 10.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-OwaConnectivity -URL https://e2k7/owa -MailboxCredential (Get-Credential NGH\Administrator)
WARNING: The test was unable to log on to Outlook Web Access because the SSL certificate did not validate. You can force the cmdlet to proceed by re-running it and specifying the -TrustAnySSLCertificate parameter.
ClientAccessServer MailboxServer URL Scenario Result Latency Error
-----
https://e2k7/owa/ Logon Skipped -1 The test was unable to log on to Outlook Web Access because the SSL certificate did not validate. You can force the cmdlet to proceed by re-running it and specifying the -TrustAnySSLCertificate parameter.
[PS] C:\Documents and Settings\Administrator>
```

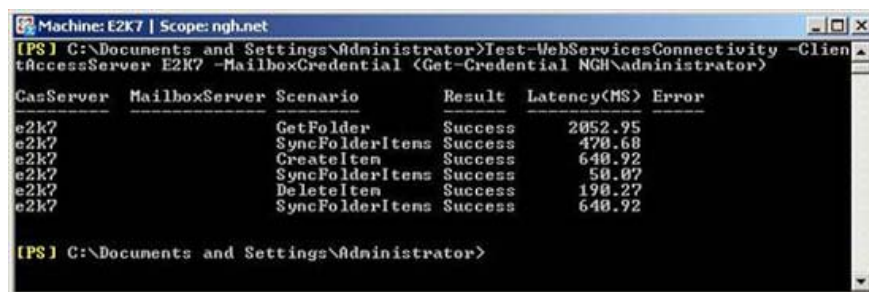

Figure 10: An error occurred when executing the Test-OwaConnectivity command

### Test-WebServicesConnectivity

To test the functionality and configuration of Outlook Anywhere, you can use the *Test-WebServicesConnectivity* cmdlet . Like the *Test-OwaConnectivity* cmdlet, this command is also a complex command because many parameters can be used. However, at the basic level, the following command can be used to test Outlook Anywhere:

*Test-WebServicesConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGHAdministrator)*

You will see that we use the *Get-Credential* command to retrieve the name and password of the corresponding account, and in this case, we will communicate with a Client Access Server, which has the name E2K7. Figure 11 shows the results of running this command, you can see the different tests performed and the latency results corresponding to them.

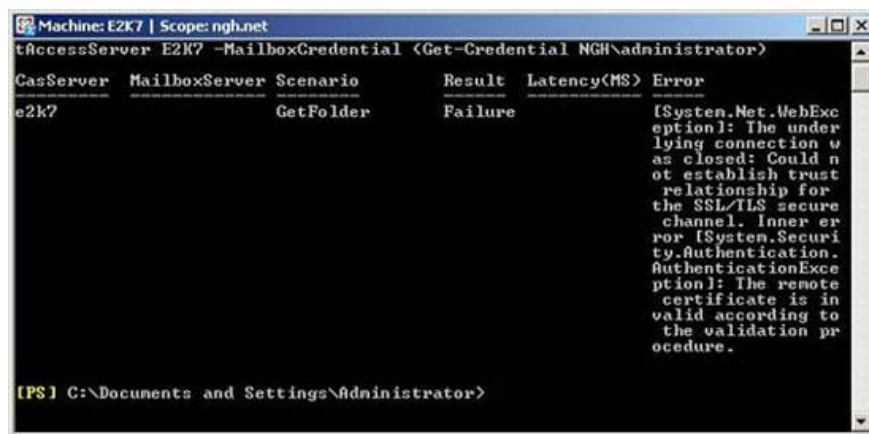

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-WebServicesConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGHAdministrator)
CasServer MailboxServer Scenario Result Latency(MS) Error
-----
e2k7 GetFolder Success 2052.95
e2k7 SyncFolderItems Success 470.68
e2k7 CreateItem Success 640.92
e2k7 SyncFolderItems Success 50.07
e2k7 DeleteItem Success 190.27
e2k7 SyncFolderItems Success 640.92

[PS] C:\Documents and Settings\Administrator>
```

Figure 11: Output of Test-WebServicesConnectivity command

This command is also very helpful in guiding you how to do this to resolve configuration issues. For example, see the output in Figure 12, where you see the error message listed that tells us there is a certificate configuration issue in the system.

```
Machine: E2K7 | Scope: ngh.net
Test-WebServicesConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGHAdministrator)
CasServer MailboxServer Scenario Result Latency(MS) Error
-----
e2k7 GetFolder Failure [System.Net.WebException]: The underlying connection was closed: Could not establish trust relationship for the SSL/TLS secure channel. Inner error [System.Security.Authentication.AuthenticationException]: The remote certificate is invalid according to the validation procedure.

[PS] C:\Documents and Settings\Administrator>
```

Figure 12: Error message of Test-WebServicesConnectivity command

### Test-PopConnectivity and Test-ImapConnectivity

These two commands are used to check the functionality of POP3 and IMAP4 services. Some of the main parameters used with these commands include *-ClientAccessServer* and *-MailboxCredential* to create a login via POP3 or IMAP4. For example, the following command will generate the results shown in Figure 13.

*Test-PopConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGHAdministrator)*

```

Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator.NGH>Test-PopConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGH\Administrator)

```

| CasServer | MailboxServer | Scenario               | Result  | Latency(MS) | Error                                    |
|-----------|---------------|------------------------|---------|-------------|--|
| E2K7      | E2K7          | Test POP3 Connectivity | Failure |             | Service 'MSExchangePOP3' is not running. |

```

[PS] C:\Documents and Settings\Administrator.NGH>_

```

Figure 13: An error occurred when executing the Test-PopConnectivity command

Here you can also see the results of the testing process as well as the latency. Looking at the *Error* column you will see a lot of useful things about what happens, because the POP3 service is disabled by default during the new Exchange 2007 installation. Therefore, to balance many things, this is What you need to consider for successful login.

```

Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator.NGH>Test-PopConnectivity -ClientAccessServer E2K7 -MailboxCredential (Get-Credential NGH\neil)

```

| CasServer | MailboxServer | Scenario               | Result  | Latency(MS) | Error |
|-----------|---------------|------------------------|---------|-------------|-------|
| E2K7      | E2K7          | Test POP3 Connectivity | Success | 164.75      |       |

```

[PS] C:\Documents and Settings\Administrator.NGH>_

```

Figure 14: Perform the Test-PopConnectivity command

In the previous part of this article, we saw how to use the `-IndexingTimeout` parameter with the `Test-ExchangeSearch` command to control the waiting period before deciding that items cannot be retrieved from the information store. . Both `Test-PopConnectivity` and `Test-ImapConnectivity` commands have the `-Timeout` parameter, which is set by default to 30s. You should check the other parameters that these test commands have.

### MonitoringContext parameter

If you have looked at the parameters available with each Test command, you will see that a parameter is always listed as an option, this parameter is called *MonitoringContext* . It is used by the Exchange Management Pack for Systems Center Operations Manager (SCOM). What this parameter does is return the test events and performance counter parameters as well as the provided information you saw from the pictures in this article.

If you want to see this information appear at the output of the commands, simply use the `MonitoringContext` parameter. This is a simple Boolean parameter and so options can be only `$true` or `$false` . If this parameter is set to `$true`, then you will receive additional information related to checking events and performance counting parameters. For example, Figure 15 shows the results of the `Test-MAPIConnectivity` command used in conjunction with the `MonitoringContext` parameter set to `$true`. Note that the specific latency values ??will get inside the *PerformanceCounters* section instead of the values ??made as shown in Figure 6.

```
Machine: E2K7 | Scope: ngh.net
[PS] C:\Documents and Settings\Administrator>Test-MAPIConnectivity -MonitoringContext $true
MailboxServer      Database          Result            Latency(MS)      Error
-----
E2K7               Mailbox Database Success           16
E2K7               Mailbox Database 2 Success           11
Events             : <Source: MExchange Monitoring MAPIConnectivity
                        Id: 1000
                        Type: Information
                        Message: All MAPI connectivity transactions succeeded.>
PerformanceCounters : <Object: MExchange Monitoring MAPIConnectivity
                        Counter: Logon Latency
                        Instance: E2K7\First Storage Group\Mailbox Database
                        Value: 16.4777, Object: MExchange Monitoring MAPIConnectivity
                        Counter: Logon Latency
                        Instance: E2K7\First Storage Group\Mailbox Database 2
                        Value: 11.2679>
[PS] C:\Documents and Settings\Administrator>_
```

### Conclude

Over the two parts of this article, we have introduced you to various Test- commands that you can use to test the configuration and operation of Exchange 2007 servers. For the whole of this article, there are many parameters that can be used along with the commands, so you should refer to these commands more fully and remember to use them when checking your Exchange environment. me

You finished reading the article "**Check Exchange 2007 with PowerShell - Part 2**" edited by the [TipsMake](#) team. We hope this article has provided you with many useful tech tips and tricks.
