5 ways to block websites on Chrome

1. Block Site
2. Ublacklist
3. Use Hosts file
 1. Edit Hosts file in Windows
 2. Edit Hosts file in Linux and Mac

1. Block Site

The best thing about Block Site is the authentication option. Once you have configured the blocked site list, you can add a password to the Settings page so that children cannot access and undo what you have blocked.

After installing the extension, open the add-on settings and add the sites you want to block. Select the **Enable Authentication** box and enter the password to block access to the installation.

wips.com
Block site

Enable functions

- Enable Block Site
- Blacklist Whitelist
- Allow sending anonymous statistics?

Authentication

UBlacklist is an easy-to-use extension that allows blocking websites from appearing in Google's search results. After installing UBlacklist, there are several ways to block websites.

First, if a website wants to block appear in the search results, you will see the ' **Block this site** ' option next to its URL. Click here and the site will not appear in the search results next time.

You can then manage your blocked sites by right-clicking the uBlacklist icon in the Chrome extension area and clicking " **Options** ". Here, you can delete sites from the block list, manually add sites, sync lists with Google Drive to use on other devices, and enter **Personal Blocklist** block lists .

3. Use Hosts file

Whether you're using Windows, Mac or Linux, you can use the Hosts file to block specific websites. It sounds a bit technical, but this is really a bad choice and can attract the attention of those who like to block websites without having to worry about third-party software. This method helps to block websites on all browsers. If you don't like this method, choose another way in the list above to block unwanted sites.

Below, how to edit the Host file to block websites on each major platform:

Edit Hosts file in Windows

How to do this, please refer to the article: [How to block a website using a host file.](#)

```
File Edit Format View Help
# Copyright (c) 1993-2009 Microsoft Corp.
#
# This is a sample HOSTS file used by Microsoft TCP/IP for Windows.
#
# This file contains the mappings of IP addresses to host names. Each
# entry should be kept on an individual line. The IP address should
# be placed in the first column followed by the corresponding host name.
# The IP address and the host name should be separated by at least one
# space.
#
# Additionally, comments (such as these) may be inserted on individual
# lines or following the machine name denoted by a '#' symbol.
#
# For example:
#
#       102.54.94.97       rhino.acme.com          # source server
#       38.25.63.10      x.acme.com              # x client host

# localhost name resolution is handled within DNS itself.
#       127.0.0.1        localhost
#       ::1             localhost

127.0.0.1 facebook.com
127.0.0.1 example.com
```

Edit Hosts file in Linux and Mac

This process is exactly the same as for Windows, except that the user needs to navigate to the '**etc**' directory to open the Hosts file.

Using one of these applications, users will have more control over which websites are allowed to appear on the browser. It's great that these extensions will help users get rid of the habit of spending time on a useless website.

Good luck!
