

# How to Share Files Between Linux Computers Using NFS

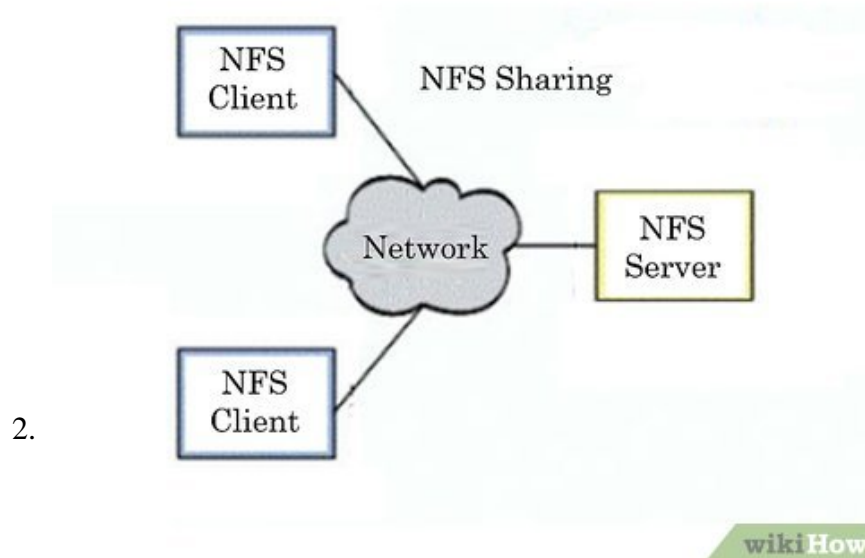

Nearly all Linux distributions come with the ability to set up a Network File System (NFS) that allows the different Linux computers on the network to easily share files. NFS is only suitable for networks comprised entirely of Linux...

Part 1 of 2:

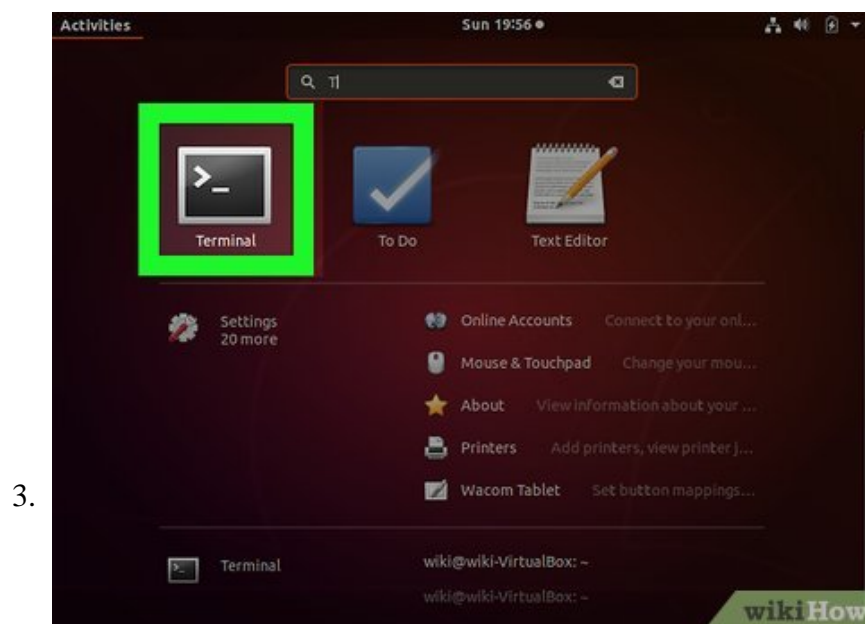

## Creating the Server

**Use NFS (Network File System) to share files between Linux computers on a local network.** If you need to share files with Windows or Mac computers, you will be much more successful using Samba.

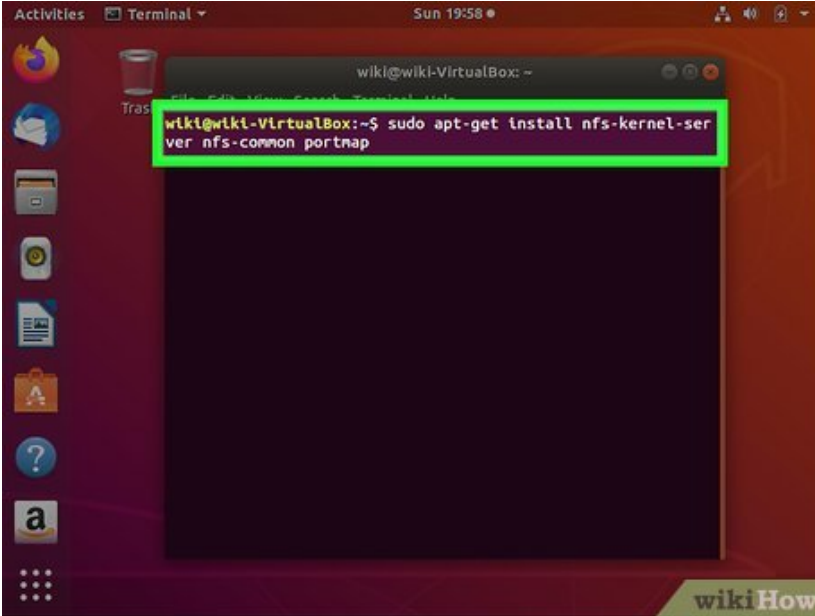

**Understand how NFS works.** When sharing files with NFS, there are two side: the server and the clients. The server is the computer that is actually storing the files, while the clients are the computers that are accessing the shared folder by mounting the shared folder as a virtual drive. NFS will need to be configured on both the server and any client that wants to connect.

**Open the terminal on the server computer.** This is the computer that will be hosting the shared files. The server computer will need to be turned on and logged in in order for clients to mount the shared folder. NFS requires using the terminal to install and configure both the server and client.

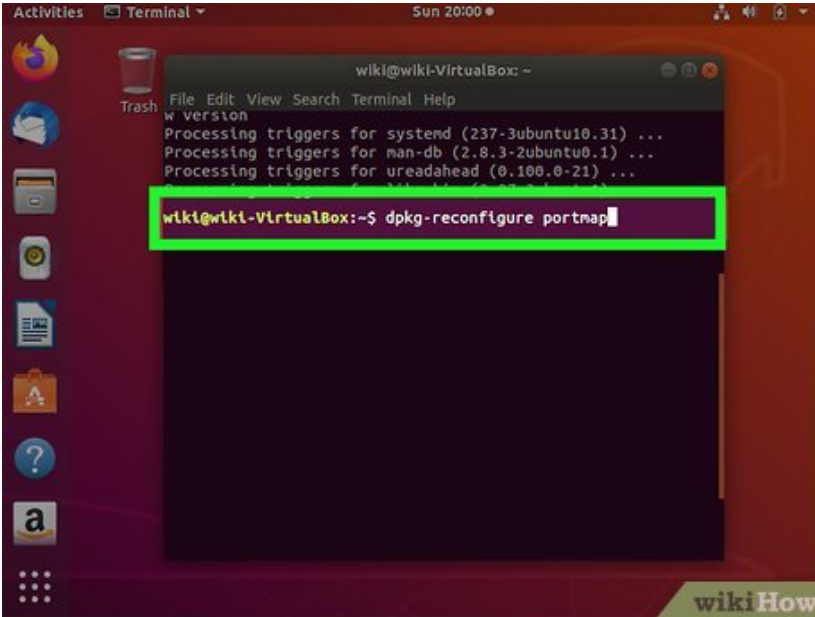

4.

A terminal window titled 'wiki@wiki-VirtualBox: ~' is shown. The command 'sudo apt-get install nfs-kernel-server nfs-common portmap' is entered and highlighted with a green box. The terminal output shows the progress of the installation, including package lists and progress bars. The desktop background is Ubuntu, and the terminal window has a menu bar with 'File Edit View Search Terminal Help'.

```
wiki@wiki-VirtualBox:~$ sudo apt-get install nfs-kernel-server nfs-common portmap
```

**Type** `sudo apt-get install nfs-kernel-server nfs-common portmap` **and press** `?Enter`. This will begin downloading and installing the NFS files on your computer.

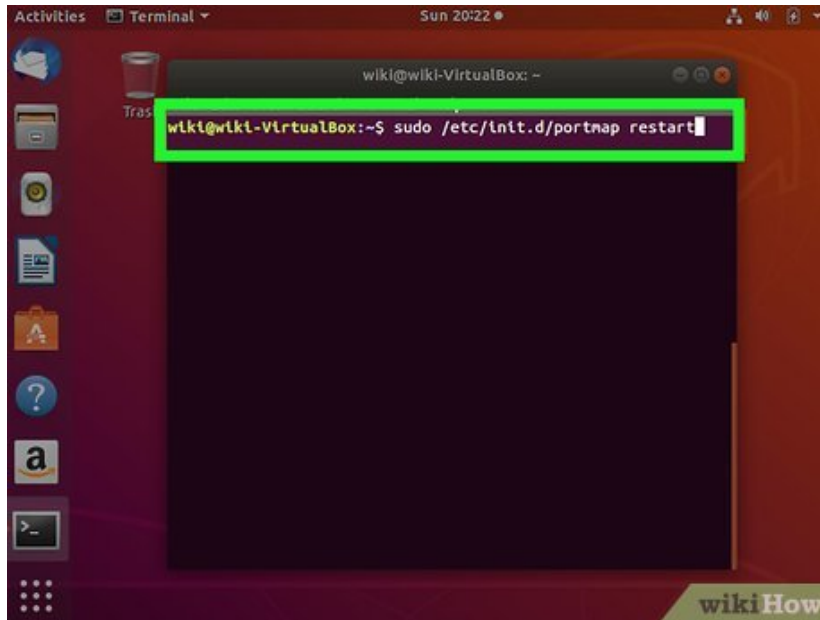

5.

A terminal window titled 'wiki@wiki-VirtualBox: ~' is shown. The command 'dpkg-reconfigure portmap' is entered and highlighted with a green box. The terminal output shows the reconfiguration process for portmap, including prompts for 'w version' and 'Processing triggers'. The desktop background is Ubuntu, and the terminal window has a menu bar with 'File Edit View Search Terminal Help'.

```
wiki@wiki-VirtualBox:~$ dpkg-reconfigure portmap
```

**After installation, type** `dpkg-reconfigure portmap`. Select "No" from the menu that appears. This will enable other computers on the network to connect to your shared folder.

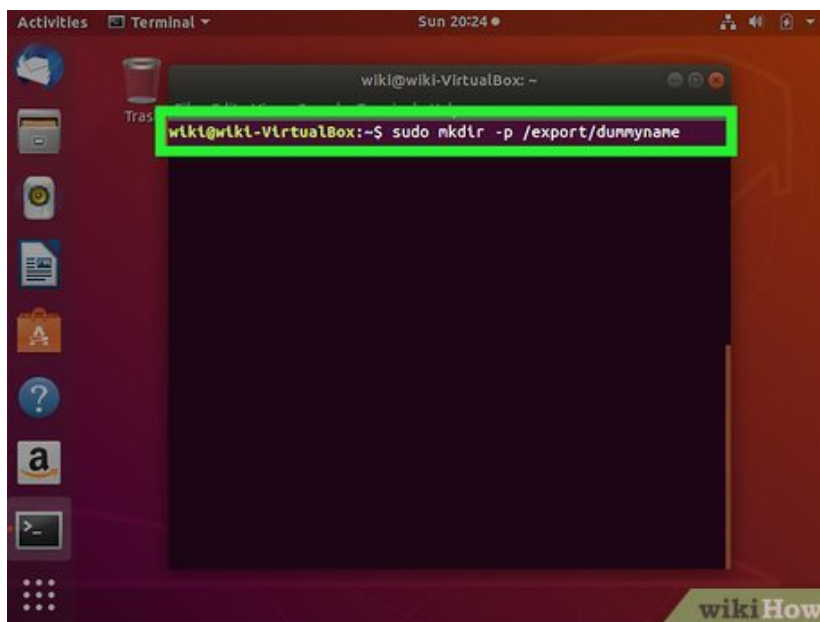

6.

A terminal window titled 'wiki@wiki-VirtualBox: ~' is shown within a desktop environment. The command 'sudo /etc/init.d/portmap restart' is typed into the terminal and highlighted with a green box. The desktop background is dark red with various application icons on the left side. A 'wikiHow' logo is visible in the bottom right corner of the terminal window.

```
wiki@wiki-VirtualBox:~$ sudo /etc/init.d/portmap restart
```

Type `sudo /etc/init.d/portmap restart` to restart the portmap service. This will ensure that your changes take effect.

7.

A terminal window titled 'wiki@wiki-VirtualBox: ~' is shown within a desktop environment. The command 'sudo mkdir -p /export/dummysname' is typed into the terminal and highlighted with a green box. The desktop background is dark red with various application icons on the left side. A 'wikiHow' logo is visible in the bottom right corner of the terminal window.

```
wiki@wiki-VirtualBox:~$ sudo mkdir -p /export/dummysname
```

**Make a dummy directory that will be used to share the data.** This is an empty directory that will direct the clients to the actual shared directory. This will allow you to change the shared directory on your server later without having to make any changes to the clients.

1. Type `mkdir -p /export/dummysname` and press `?Enter`. This will create a directory named `dummysname` that the clients will see.

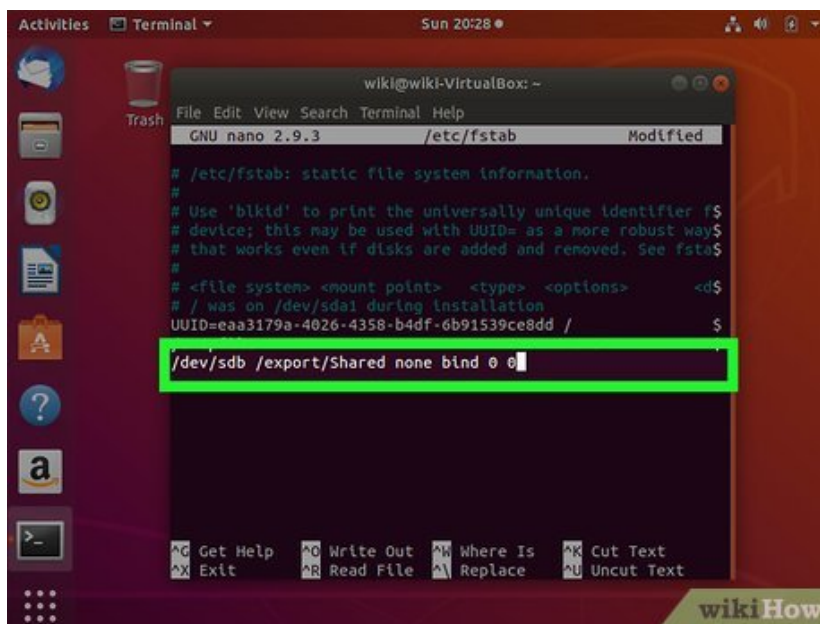

8.

```
wiki@wiki-VirtualBox: ~  
File Edit View Search Terminal Help  
GNU nano 2.9.3 /etc/fstab  
# /etc/fstab: static file system information.  
#  
# Use 'blkid' to print the universally unique identifier for a  
# device; this may be used with UUID= as a more robust way  
# that works even if disks are added and removed. See fstab(8).  
#  
# <file system> <mount point> <type> <options> <dump> <pass>  
# / was on /dev/sda1 during installation  
UUID=aaa3179a-4026-4358-b4df-6b91539ce8dd / $  
/swapfile none $  
File '/etc/fstab' is unwritable  
^G Get Help ^G Write Out ^W Where Is ^K Cut Text  
^X Exit ^R Read File ^\ Replace ^U Uncut Text
```

Type `pico /etc/fstab` and press `? Enter`. This will open the `/etc/fstab` file and allow you to automatically mount the shared drive whenever the server boots up.

9.

```
wiki@wiki-VirtualBox: ~  
File Edit View Search Terminal Help  
GNU nano 2.9.3 /etc/fstab Modified  
# /etc/fstab: static file system information.  
#  
# Use 'blkid' to print the universally unique identifier for a  
# device; this may be used with UUID= as a more robust way  
# that works even if disks are added and removed. See fstab(8).  
#  
# <file system> <mount point> <type> <options> <dump> <pass>  
# / was on /dev/sda1 during installation  
UUID=aaa3179a-4026-4358-b4df-6b91539ce8dd / $  
/dev/sdb /export/Shared none bind 0 0
```

Add `sharepath dummyspath none bind 0 0` to the end of the file. Replace `sharepath` with the location of the shared drive, and replace `dummyspath` with the location of the dummy directory you created earlier.

1. For example, to share the `/dev/sdb` drive with the clients using the dummy directory created earlier, you would type `/dev/sdb /export/Shared none bind 0 0`. Save the changes to the file.

10.

**Open the `/etc/exports` file.** You will need to add your dummy directory as well as the IPs that are allowed to access it to this file. Use the following format to share with all the IP addresses on your local network: `/export/dummyname`  
`192.168.1.1/24(rw,no_root_squash,async)`.<sup>[1]</sup>

11.

**Use the `sudo /etc/init.d/nfs-kernel-server restart` command to restart the NFS server.**<sup>[2]</sup>

Part 2 of 2:

## Connecting the Client Computers

1.

Open the terminal on the client computer.

2.

Type `sudo apt-get install portmap nfs-common` and press `? Enter` to install the NFS client files.

3.

**Create the directory that the shared files will be mounted in.** You can name this whatever you'd like. For example, you can type `mkdir /sharedFiles` to create a folder called "sharedFiles".

4.

**Type `pico /etc/fstab` to open the `/etc/fstab` file.**

5.

Add `serverIP:sharedDirectory nfs rsize=8192,wsz=8192,timeo=14,intr` to the end of the file. Replace `serverIP` with the IP address of the NFS server computer. Replace `sharedDirectory` with the dummy directory you created on the NFS server and the local directory you just created. Leave the rest of the values as they are for now.

- Using the above examples, the line might look like: `192.168.1.5:/export/Shared /sharedFiles nfs rsize=8192,wsz=8192,timeo=14,intr`.

6.

Type `sudo /etc/init.d/portmap restart` to restart portmap and use the new settings. The drive will automatically mount each time the computer reboots.

7.

**Test the drive by manually mounting it before restarting.** Type `mount -a` and then `ls /sharedFiles` to see if the shared files are displayed.

8.

**Repeat this process for each connecting computer.** You should be able to enter the same settings and successfully connect.<sup>[3]</sup>
