

Mobler 'super devastating' computer worm is back!

Security firm F-Secure has warned that there is a 'ancient' computer worm called Mobler reappearing and spreading on the Internet. Once infected, the Mobler worm will copy a copy of it

Security firm F-Secure warned that there was a "ancient" computer worm called Mobler reappearing and spreading on the Internet.

Once infected on the system, the Mobler worm copies a copy of it to all the system's writable storage devices such as floppy disks, USB memory sticks and some other folders on the hard drive.

Therefore, one of the signs to identify a Mobler worm system is that the floppy drive automatically activates even if there is no disk in the drive.

However, this worm needs to have the impact of users, it will begin to promote its disastrous ability.

The Mobler worm also hides itself in the Windows directory and can host a denial-of-service attack. The first victim of this denial-of-service attack is the Bina Sarana Informatika website.

Not only that, every time a copy of it is copied to another place, it is renamed to avoid detection. Even the files in the infected folder will be renamed.

The Mobler worm released some files to the Windows System folder such as *autorun.inf* , *black.app* , *black.html* , *black.ico* , *black.jpg* , *black.txt* , *makesis.exe* and *system.exe* . Also in this folder, the Mobler worm will create

some compressed files such as *Black_Symbian.SIS* and *Black_Symbian.PKG* .

Once infected on your computer system, the worm Mobler also disables the *Windows Task Manager* and *Registry* tools, *Folder Options* and *Search* or the ability to block some application files from being started by *RUN* .

Security vendor warns users not to open messages with attachments and unknown sources or run any suspicious software on storage devices such as USB sticks or floppy disks.
