

## Read / write File in C ++

So far, we have used the `iostream` standard library, provided `cin` and `cout` methods to read from Standard Input and write to the corresponding Standard Output.

So far, we have used the **`iostream`** standard library, provided **`cin` and `cout`** methods to read from Standard Input and write to the corresponding Standard Output.

This chapter will show you how to read and write a file. This requires another C ++ Standard Library, **`fstream`** , which defines three new data types:

Data type Description  
`ofstream` This data type represents Output File Stream and is used to create files and to record information to those files  
`ifstream` This data type represents Input File Stream and is used to read information from the file  
`fstream` This data type generally represents File Stream, and has the capabilities of both `ofstream` and `ifstream`, meaning it can create files, write information to files and read information from files  
 To perform file processing in C ++, you include header files `<fstream.h>` and `<string.h>` in the source file of your C ++ program.

### Open a File in C ++

A file must be opened before you can read information from it or write information to it. Or the **`ofstream`** object or **`fstream`** object can be used to open a file with the purpose of writing or `ifstream` object is used to open the file for reading purposes only.

Here is the standard syntax for `open ()` function, which is a member of `fstream`, `ifstream` and `ofstream` objects in C ++:

```
void open ( const char * filename , ios :: mode );
```

Here, the first parameter specifies the name and location of the file to be opened and the second parameter of the **`open ()`** member function defines the mode in which the file should be opened.

Download mode :: Append Mode `app`. All output to that file is appended to the end of that file  
`ios :: ate` Open a file for output and move read / write control to the end of the file  
`ios :: out` Open a file to write  
`ios :: trunc` If this file already exists, its contents will be truncated before opening the file.

You can combine these two or more values together or together (use `|`). For example, if you want to open a file in write mode and want to cut (truncate) it in case it has exists, you follow the following syntax:

```
ofstream outfile ; outfile . open ( "file.dat" , ios :: out | ios :: trunc );
```

In the same way, you can open a file for the purpose of reading and writing as follows:

```
fstream QTM ; QTM . open ( "file.dat" , ios :: out | ios :: in );
```

## Close a File in C ++

When a C ++ program finishes, it automatically closes all Streams, frees all allocated memory and closes all open files. But it is a good practice for a programmer to close all open files before the end of the program.

Here is the general syntax for **close ()** function in C ++, which is a member of **fstream**, **ifstream** and **ofstream** objects in C ++:

```
void close ();
```

## Record File in C ++

While programming C ++, you write information to a file from your program using the thread insertion operator (**>>**), just like when you use that operator to create output information to the screen. The only difference is that you use an object **ofstream** or **fstream** in C ++ instead of a **cout** object in C ++.

## Read a File in C ++

You read information from a file in your C ++ program using the thread extraction operator (**>>>**), just like you use that operator to enter input information from the keyboard. The difference is that you use an **ifstream** or **fstream** object instead of using the **cin** object in C ++.

## Example of Reading and Writing Files in C ++

The following C ++ program opens a file in read and write mode. After writing the information entered by the user to a file **qtm.dat**, the program reads the information from that file and creates the output on the screen:

```
#include <fstream> using namespace std ; int main () { char data [ 100 ] ; //
```

Compiling and running the above C ++ program will produce the following results:

```
Ghi du lieu toi file!  
Nhap ten cua ban: TranMinhChinh  
Nhap tuoi cua ban: 25  
=====  
Doc du lieu co trong file!  
TranMinhChinh  
25  
-----
```

The example above uses additional functions from the **cin** object, like the **getline ()** function to read the line from the outside and the **ignore ()** function to ignore the extra characters to the left of the previous read command.

## Location file pointer in C ++

Both `istream` and `ostream` objects provide member functions to redefine the file-position pointer. These member functions are **`seekg`** (seek get) for `istream` and **`seekp`** (short for seek put) for `ostream` in C ++.

The parameter for **`seekg`** and **`seekp`** is a **`long int`** . The second parameter can be specified to guide the search direction. The search direction can be `ios :: beg` (default) to locate the starting part of a **`Stream`** , `ios :: cur` to determine the location relative to the current location in a **`Stream`** or `ios :: end` to determine the location relative to the end of a `Stream` in C ++.

The file location pointer is an integer value that determines the location in the file, calculating the number of bytes from the starting position of the file. Here are some examples to determine the location of file location pointers in C ++:

```
// xac dinh vi tri byte thu n cua doi tuong file doi_tuong_file . seekg ( n
```
