

# South Korea has a similar pattern of deaths due to Covid-19 to China, showing that the disease is very dangerous for the elderly

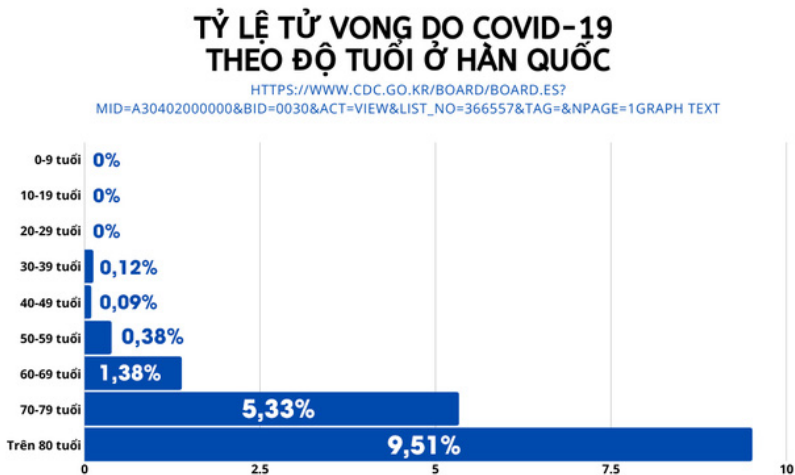

The latest epidemiological statistics by the end of last week drew a model showing Covid-19 mortality by age group in South Korea almost identical to China. The most serious disease affects the elderly over 70 years old

The Covid-19 pandemic has affected more than 100 countries and territories, infecting more than 167,000 people and killing 6,506 of them.

In South Korea, the Centers for Disease Control and Prevention has continuously issued regular reports on the number of cases and deaths from Covid-19. According to the most recent report up to March 16, there were 8,236 patients with Covid-19 in South Korea, with 75 deaths.

In particular, the latest epidemiological statistics by the end of the week before March 15 drew a model that shows that Covid-19 mortality by age group in Korea is almost identical to China. This disease affects most people over 70 years old.

The younger the child, the lower the death rate due to Covid-19. South Korea has not recorded any deaths from patients under the age of 30 with Covid-19.

According to figures as of March 15 of KCDC

According to a report on March 15, the average death rate due to Covid-19 in South Korea was 0.92%, much lower than in China, currently at 3.9%.

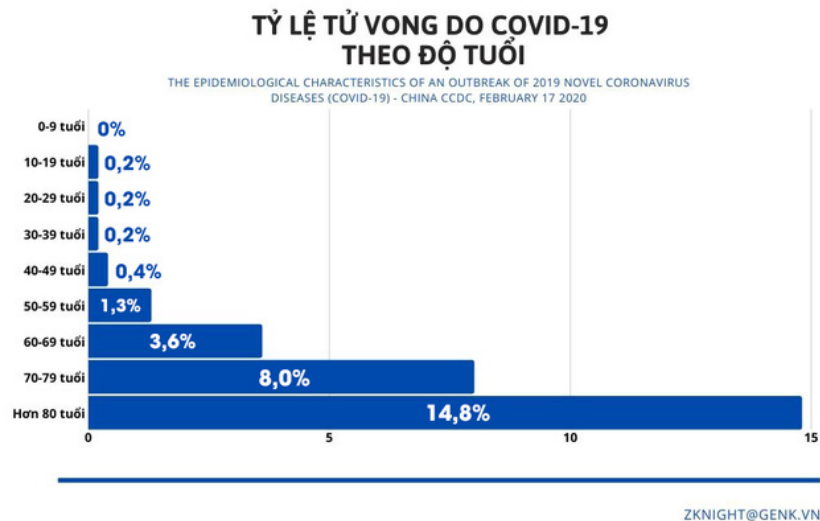

A key factor in the success of the epidemic control in Korea is that they have implemented a thorough testing policy and found all those infected with the virus. In contrast, many cases of mild illness in other countries may not have been tested or omitted.

While South Korea reported 2,811 cases of Covid-19 infection under the age of 30, no deaths were recorded among them. Only one patient between the ages of 30 and 39 died and another patient aged 40 to 49.

However, elderly patients are more likely to die from Covid-19. By the end of last week, the proportion of patients over 80 years of age dying from the disease in Korea was 9.51%. In the age group of 70-79, the figure is 5.33%.

The higher death rate among elderly patients strengthens the trend of the attack on Covid-19's elderly population.

This has been observed in a statistical model in China, whereby the Centers for Disease Control and Prevention has compiled a data set of 72,314 cases reported in this country to see if any. up to 14.8% of patients died from Covid-19 over 80 years old.

The death rate due to Covid-19 in China, according to CCDC. Data from the study was published on February 17.

Although the Covid-19 mortality rate in Korea is much lower than that of China, the age patterns of these patients appear to be surprisingly similar to the Chinese chart.

If this model continues to be recognized in other countries, it will certainly reinforce the danger of Covid-19 to countries with an aging population structure. Typically, Italy, the country with the oldest population in the world, currently has the largest number of Covid-19 deaths among countries outside of China.
