

Super Earth's most dangerous volcano can 'explode' soon causing the biggest eruption in history

Super volcano Campi Flegrei in Italy is the most dangerous volcano on the planet today. It has an accumulation of energy that is about to reach the boom stage, creating the most powerful volcanic eruption in the history of forming Earth.

Super volcano Campi Flegrei in Italy is the most dangerous volcano on the planet today. It has an accumulation of energy that is about to reach the boom stage, creating the most powerful volcanic eruption in the history of forming Earth.

1. The mysterious "death" lake in Africa takes more than 1700 lives in one night
2. What is the most devastating natural disaster that the earth has experienced?

500 years ago, Campi Flegrei had erupted tons of lava and a thick column of black smoke covered the sky for 8 days. Even a mountain called Monte Nuovo was created from a layer of rock whose lava erupted.

During the past 67 years, the pressure at this super volcano is constantly increasing, making the experts worry that it will once again explode. And according to calculations, this may be the largest volcanic eruption in Earth's history.

Campi Flegrei, super dangerous volcano can erupt at any time.

After studying how the rock layer broke and moved at Campi Flegrei, experts believe that this volcano is approaching the most serious phase, any impact can activate it. A terrible explosion will occur and the authorities cannot do anything else soon to prepare for any possible circumstances.

The terrible power of super volcano

Conventional volcanoes look like a mountain, but super volcanoes are different, it spreads over the ground creating a volcanic geological area like the Yellowstone Range (America's largest volcanic sequence).

When an ordinary volcano erupts too much lava, it collapses and creates a giant crater, with vents, vents and sulfuric acid forming super volcanoes.

2000 years ago, Campi Flegrei was formed from a massive massive volcanic collapse. Even the researchers said that this may be the cause of the extinction of the Neanderthals.

Campi Flegrei super volcano stretches to 100km², consists of 24 volcanoes, and some submerged mountains under the Mediterranean Sea. In the past, Campi Flegrei had been erupting about 35,000 years ago, and a smaller explosion in 1538.

And according to experts, this super volcanic energy level is accumulating and about to reach an explosion. They did not know how long this unrest would last and the exact time it would officially explode, as this depends on the amount of magma boiling at a depth of up to 3,000 meters from the center of the ridge.

When this amount of magma reaches its peak, the super volcano Campi Flegrei will explode. At least 360,000 people in the neighborhood, and nearly 1 million people around Naples will be affected by this natural disaster.
